# Description

## Entities

## Relationships

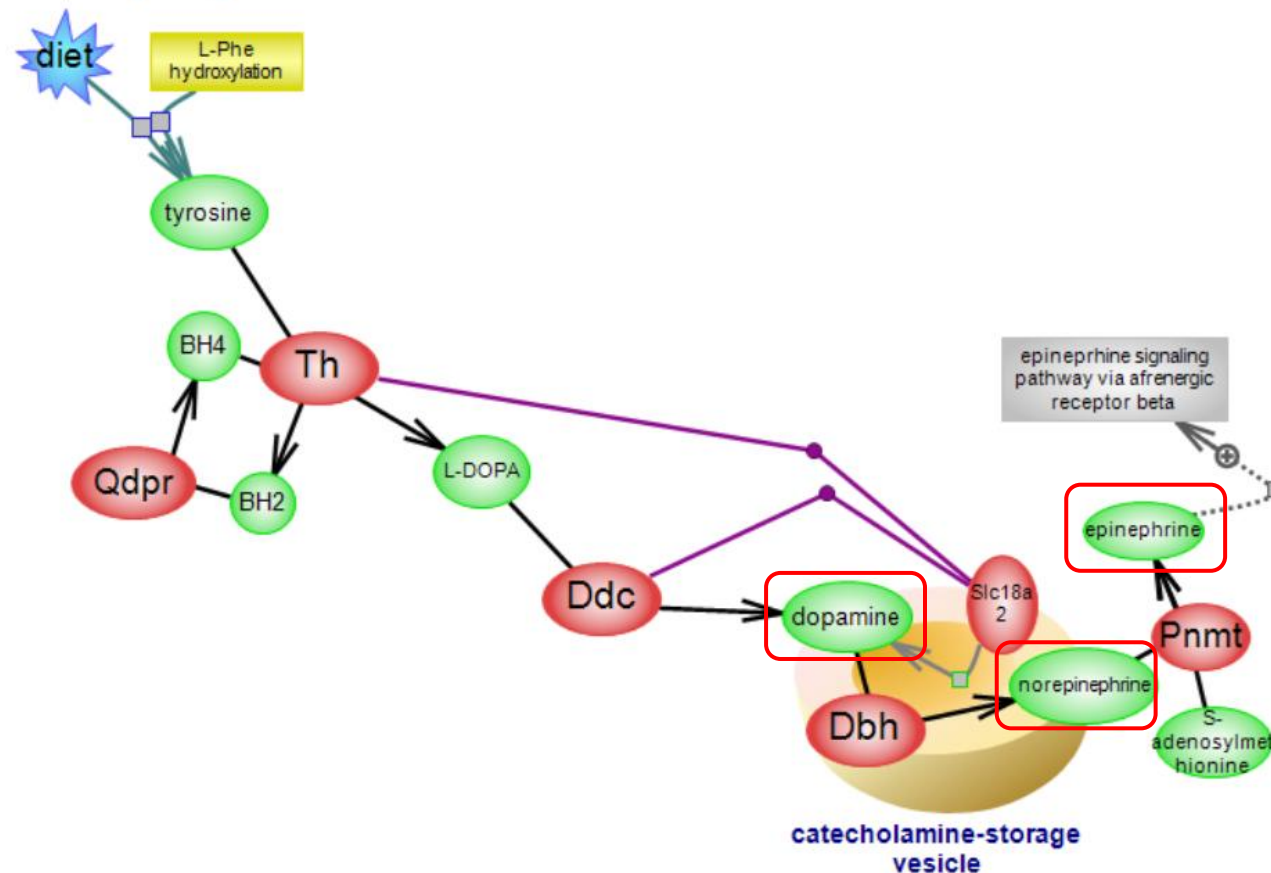

## Shapes

The synthesis and release of catecholamines dopamine, norepinephrine and epinephrine are triggered by various but distinct conditions and stresses. Norepinephrine and epinephrine, also known as noradrenaline and adrenaline, act as neurotransmitters and hormones. They signal via various adrenergic receptors, G protein-coupled receptors (GPCR) which couple to distinct G alpha subunits of heterotrimeric G proteins. Stresses such as cold and pain prompt the synthesis of norepinephrine in sympathetic...(more)

## How PW diagrams were created at RGD

- Generate a diagram draft based on reviews
- Make GO, disease/phenotype annotations of these “pathway genes”
- Use Elsevier (originally Ariadne) Pathway Studio software to create PW diagrams
- Upload the PW diagrams to database using RGD pathway diagram tool to link genes, small molecules to RGD web pages or outside resources. And generate PW pages and components on the page.
- RGD also creates gene-pathway annotations for pathway terms that do not have diagrams.

Diagram illustrating the components of a cell signaling pathway:

- Nuclear receptors
- Kinases
- Phosphatases
- Extracellular protein
- Ligands
